The hardware underneath is an old 2012 MacMini with a 2.3GHz Core i7 processor. Both compilation time and file size scale roughly proportionally to both number of methods and types.

A Multipolygon represents a set of outer and inner polygons, which basically means two sets of Way objects. However, as it turned out in 2013, this niche was already dead and everything moved into CMS-style systems with backend programming languages, databases, and other cruft.

The intention was to find a simple WYSIWYG design system that would allow to slam together some content, export it as plain HTML files and then upload them to a server. In this post I, roughly model the situation with synthetic code generation. For such a simple website nothing else was required.

The Model class transforms the input XML file into a set of linear containers which hold all information required to render the map. To complicate matters, OSM does not mandate a strict order of Ways declaration and only requires that a closed polygon should be composable out of a given set. The problem was to make it lazy loading and somewhat responsive while keeping everything as simple as possible.
